Muhammad K Naeem.: MD

OBJECTIVE:

If you consume more energy (calories) than you expend, you will gain weight. Excess calories are stored throughout your body as fat. Your body stores this fat within specialized fat cells (adipose tissue) — either by enlarging fat cells, which are always present in the body, or by creating more of them. Obesity is an important public health issue, characterized by the dissemination of diseases such as hypertension, diabetes mellitus type II, cardiovascular risk diseases such as atherosclerosis, dyslipidemia, and acute and chronic inflammatory processes, among others, besides favouring great physical and aesthetic dissatisfaction. Fat removal and body reshaping are increasingly popular cosmetic procedures. Currently, liposuction is the most common and effective procedure for body contouring. Given the invasive nature of liposuction and its inherent risks, there has been continuous research for the development of non-invasive methods. The development of a noninvasive method that operates in the reduction of the fat layer called "cryo-lipolysis" has been employed for the selective destruction of fat cells. This non-surgical approach uses controlled cooling to decrease subcutaneous fat without damaging surrounding tissues. This study is to find if using gaseous cryotherapy treatments using KaasenLife by TruCryo can achieve

inch loss around the candidate's stomach area.

Kaasen Life device:

The KaasenLife device delivers a controlled spray burst of CO2 to the surface of the skin to cool the area down rapidly. The device has many safety features that monitor the skin temperature and proximity to make sure the spray is applied at the correct distance and the temperature drop is constantly monitored. The device comes with a variety of different nozzles, each with a different aperture which varies the speed at which the CO2 spray comes out and hits the surface of the skin.

The trained therapist makes sure the optimum distance and constant movement of the spray is maintained to prevent surface tissue damage.

The skin surface temperature of the area being treated is recommended to be around 4°C and below. An A5 size area of the body generally takes between 30 to 90seconds to get down these temperatures.

SCIENTIFIC BASIS:

Cryolipolysis is a completely different modality from techniques like that of Coolsulpting which uses controlled cooling plates to treat the area. The principle behind this technology exploits the premise that adipocytes are more susceptible to cooling than other skin cells.

This study is carried out using KaasenLlfe, to see if the treatment protocol triggers controlled fat cell death due to its ability to spray CO_2 at -78°C, under 50 bar pressure, cooling the targeted treatment area down to 4°C and below rapidly.

Cryo-apoptosis is a term used for a treatment using cold temperatures to destroy fat cells by freezing them within the temperature range of +4 to +8°C.

CANDIDATES:

18 candidates consented to be part of the study, all of which were unhappy with the fat around their waist. All clients stated that they had not changed their diet, increased their normal exercise, or changed their lifestyle routines during the trial.

The safety and comfort of each client were closely monitored throughout their treatment.

No other medication or modality equipment was used as part of the trial.

18 patients attended weekly appointments and completed a course of ten treatments, once per week over 10 weeks.

Consultation made sure candidates did not have eating disorders, body dysmorphia, health, any other mental illness or physical contra-indications

METHOD:

The trained user of the device rapidly cools the skin temperature and maintains the temperature, to around 0°C throughout the application of the CO2 spray. This is achieved through their technique of moving the device around the area when using KaasenLife device and the nozzle selected. In all cases the Black nozzle was chosen because of its high pressure and larger aperture to allow more gas to pass through it The temperature can be monitored on screen by the incorporated sensors within the device and also a light is shone onto the treatment area which changes from white to blue to indicate that the user is in the optimum temperature range. The device also has a proximity sensor and can monitor the distance of the spray and make sure there is no risk of burning the skin. Each Client was photographed and measured around the waist at the start of the course of treatments. The treatment involved spraying the front of the stomach and the flanks until a temperature of 4°C was achieved. Each week the treatment would be carried out using the same method and the candidate was again measured and photographed.

Illustration of Co2 spray being applied to the surface of the skin

RESULTS. Between April, May, and June 2022 results were as below:

After 10 treatments carried out over 10 weeks, we observed a significant reduction in waist measurements with the candidates.

Conclusion:

With all candidates we observed a significant reduction when measuring around the waist. The skin quality was also observed to be tighter than at the start of the course of treatments.

OBSERVATION. All patients achieved inch loss after just the first treatment. This is because the skin tightens as a reaction to the cold temperatures.

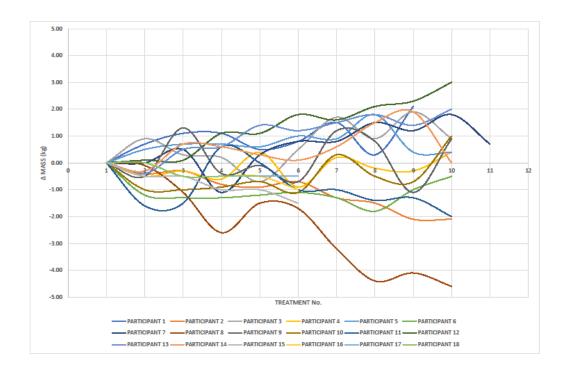

All patients after 10 weeks candidates had achieved a smaller waist with one client having 4" loss around the waist.

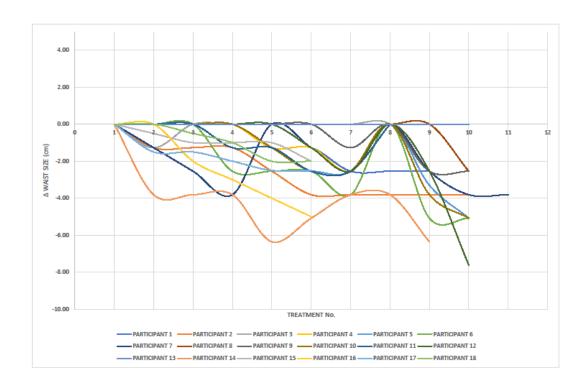

The quality of skin was observed to be firmer.

All Patients also saw a visible firming and tightening of the skin and felt invigorated post-treatment.

All patients reported a feeling of well-being following the procedure and felt they would recommend KassenLife to friends and family for body sculpting.

DISCUSSION:

The aim of the study was to see if cold triggers a response that causes the adipocyte programmed death (apoptosis) and gradually lessens the fat layer and from our observations we could see inch loss around all candidates. Cryo-apoptosis effects are not immediate; however, statistically significant reduction may be obtained within approximately two months from application. Apoptosis of fat cells (adipocytes) is initiated when these cells are cooled to temperatures below +4°C.

Our method showed the protocol could be an effective treatment for rapid inch reduction, skin toning and tightening. More studies are currently being carried out to see the long-term results of Cryo-Sculpting. Care should be taken to also look at the patient's diet and lifestyle which also are very important factors obviously in improving and maintaining the results. The process of using "Kaasen Life" for Fat Freezing was a simple and straightforward procedure.

The latest scientific research into cryo-stimulation and cold stress and apoptosis using cold temperatures suggests it provides multiple beneficial effects on the human body. From the perspective of this trial, we were most interested in the following processes and outcomes.

- Cryo-Apoptosis the permanent destruction of fat cells, which are then flushed through the lymphatic system
- Increased browning of adipose tissue (fat cells); a process which makes the fat cells metabolise more efficiently, and so fat loss occurs more quickly
- Accelerated microcirculation (the smallest blood vessels which supply the skin), which supports better oxygenation of derma cells and encourages collagen production for healthier skin
- Removal of dead skin to stimulate new smoother skin growth
- The reaction to cold causing vasoconstriction and dilation of blood vessels to flush toxins and impurities away
- Increases dopamine which boosts metabolism and energy levels

To confirm these biological responses more studies would be needed to carry out.

Another biological mechanism mentioned would also need more exploration into would be concerning a beige effect that cold temperatures have on fat. There are two types of adipose or fat tissue: brown and white. White adipose tissue stores energy - this is also the type of fat that can add inches to your waist and thighs. Brown adipose fat, which is primarily located around the neck and collar bones, is metabolically active and can burn or oxidise white adipose tissue,

Some Cryotherapy studies have shown that regular cryotherapy sessions can activate the brown adipose fat and muscles. Once activated, they release two hormones: irisin and FGF21. These hormones then burn white fat tissue and help you lose weight.

Studies have shown that what activating irisin does is, that it converts white fat into healthier brown fat - this improves the glucose tolerance of the body.

Case Reports in Dermatological Medicine promise results have been confirmed in studies; therefore, it seems to be an excellent alternative for localized fat reduction without major adverse effects.

Scientific studies also indicate that using Cryo Stimulation induces triggers apoptosis, destroying fat cells permanently which are then flushed through the lymphatic system. More studies need to be done to discover if Cryo Sculpting also causes the browning of stubborn fat (adipose tissue) and helps in burning off fat.

To improve the protocol in future studies, post-treatment, a light-pressure massage to aid the process of flushing out the destroyed fat cells through the lymphatic system maybe something that could benefit the protocol.
